X-SIM PROFILER 2.1

File menu **My simulator** **192.168.1.157** **Open manual** **Weblink**

Start

Synaptrix IO Output

Universal Serial Output

Statistic Logfile

Interface for external position control (like SPS profibus, the old Rock'n'Ride interface or motion control boxes)

First find one free comport and add it to the list: Porta di comunicazione (COM1)

Device path: \\?\acpi#pnp0501#1#(86e0d1e0-8089-11d0-9ce4-080003e301f73)

For non ISA comport (USB) or comport's higher than 4 write the path \\.\COM1 or \\.\COM9 in the comport selection box above.

Calculate the output of each axis and choose type of output. (output is normally 0 to 255 as character, 127 is middle position)
If you like to use a axis value with 8bit resolution and another resolution, then you have to duplicate this axis.

Left = ~a01~ value = (value / *) +

8 bit resolution (0 ... 255) LowRes 16 bit resolution (0 ... 65535) MedRes 32 bit resolution (0 ... 4298769224) HighRes

binary output (e.g. one character) decimal output (e.g. 3 or 123) hexadecimale output (e.g. 01FA)

Tip: If only 4 bits instead of 8 bits are used, use divider /16 and multiply it with the offset needed (e.g. 2 Bit = *4) then use the last value to set a constant bitmask. Also you can invert output by multiply with -1 and add 255.

Tutorial "How to use USO parser"

Output Protocol Parser: (the values that will be send every cycle)

Use character that have to be send to the receiving device like before and after the axis value.
Use ~a01~ or ~a02~ if you want to insert the x or y axis at this position, declared as the characters above.
For special values or character like return use ~n~ where n is an ascii number between 0 to 255. Return would be ~13~.
Linefeed ~10~.

Example: The device needs a Character "S" for send, the x axis value and then return to proceed:

Select comport to edit: COM1

Set comport speed and control: 115200 8 NOPARITY 1ONESTOPBIT lock ports on startup

Datapacket sent at simulatorstart:
and wait for HW init 0 ms

Datapacket with axisinformations: AB~255~~a01~~a02~
with a pause of 33 ms /

Datapacket sent at simulatorstop:
and wait for HW stop 0 ms

X-SIM PROFILER 2.1

Interface for external position control (like SPS profibus, the old Rock'n'Ride interface or motion control boxes)

First find one free comport and add it to the list: Porta di comunicazione (COM1) Refresh

Device path: \\?\acpi#pnp0501#1#86e0d1e0-8089-11d0-9ce4-08003e301f73

For non ISA comport (USB) or comport's higher than 4 write the path \\.\COM1 or \\.\COM9 in the comport selection box above.

Calculate the output of each axis and choose type of output. (output is normally 0 to 255 as character, 127 is middle position)
If you like to use a axis value with 8bit resolution and another resolution, then you have to duplicate this axis.

Right = ~a02~ value = (value / 1 * 1) + 0

8 bit resolution (0 ... 255) LowRes 16 bit resolution (0 ... 65535) MedRes 32 bit resolution (0 ... 4298769224) HighRes
 binary output (e.g. one character) decimal output (e.g. 3 or 123) hexadecimale output (e.g. 01FA)

Tip: If only 4 bits instead of 8 bits are used, use divider /16 and multiply it with the offset needed (e.g. 2 Bit = *4) then use the last value to set a constant bitmask. Also you can invert output by multiply with -1 and add 255.

Datapacket with axisinformations: AB~255~~a01~~a02~ with a pause of 33 ms /

Datapacket sent at simulatorstop: and wait for HW stop 0 ms

X-SIM PROFILER 2.1

Within this dialog you have to provide the program informations about how to calculate a sender input value to a result value which can be used in the output setup. Therefore you have to choose a math plugin and fill out the popup dialog if needed. For more DOF you have to mix here the values to a fitting result. Also you can specify how much virtual axis you will need. A axis can be a simulator hardware actuator axis or a simple gauge dashboard system.

Show math setup of axis: Left

Found math plugins:

- 2DOF-MCA
- Threshold (Collision)
- Copy and combine
- Output 1:1 (GForce)

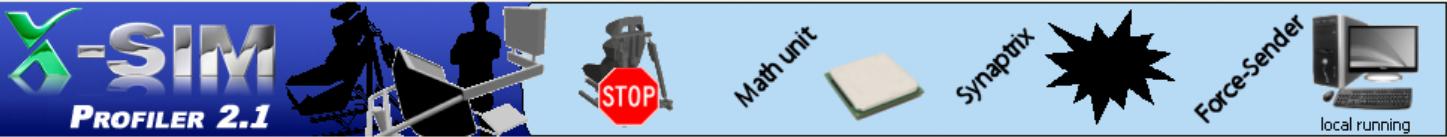

Add line Edit line Remove line Move one line up Move one line down Add a desktop slider Show math sliders Top

Step by step calculation table:

#	math plugin	result	slider	value	value	value
1	Output 1:1 (GForce)	<input type="text"/>	<input type="text"/>	value# 26	invert	true
2	Output 1:1 (GForce)	<input type="text"/>	<input type="text"/>	value# 27	invert	true
3	Output 1:1 (GForce)	<input type="text"/>	<input type="text"/>	value# 25	invert	false
4	Percent scaler	<input type="text"/>	<input type="text"/>	percent 50	n.a.	n.a.
5	Calibration offset	<input type="text"/>	<input type="text"/>	Current: 0 %		

Calibration offset of this axis: Symmetric offset (reduce range) Asymmetric axis offset (full range)

Realtime result analyzer: Green shows selected result, blue final result and grey color shows you the reduced range

Calibration offset of this axis: 0 Symmetric offset (reduce range) Asymmetric axis offset (full range)

Realtime result analyzer: Green shows selected result, blue final result and grey color shows you the reduced range

Simple resize math setup (G-Forces, curves and gauges)

First step (choose sender input value)
Choose one Force-Sender input value displayed in the input setup:
Sender input 25: Effect 25: Lateral force
 Invert input value Play override (normally set blank)

Second step (set range parameter)
Choose the minimal and maximal numerical value of the chosen Force-Sender input value. This will prevent spike values.
Maximum value: 2000000
Minimum value: 200
 Split negative and positive
Minimum value -: 200
Maximum value -: 2000000
 Use automatic maximum adjustment Use automatic minimum adjustment (10%)

Third step (set influence to axis)
Choose intensity of this value to the axis in percent: 50 %
Adjust smoothness only, if your value is fidgety: (Current setting: off)
smooth movement is given in seconds from minimum to maximum value of this axis
weak/ off smooth
 add result value multiply result value overwrite result value
 overwrite result if bigger than zero (used as trigger)

Cancel

This math plugin is used for an 1:1 translation of an force-sender input value to a specified hardware output. Therefore it will be resized to fit the output axis. You can also cut too big values. Normally this plugin is used for realistic values out of a game, which don't need any calculation and therefore can be used directly for an output of e.g. an actuator. An example are the game plugins of force-sender, which carry G-force values like lateral or longitudinal forces.

Using gravity (G) effects creates a constant force to your body by moving the simulator in contrariwise direction to the direction your vehicle moves in order to simulate the real G-forces. The intensity can be regulated. The effect will be initialised only if the value rises above the minimum value. Maximum value increases automatically or can be given fixed. Split the maximum if there is a greater acceleration value than the brake value.

Hint: the standard settings of this dialog will help you with a fast detection and can be accepted for beginners.

Simple resize math setup (G-Forces, curves and gauges)

First step (choose sender input value)

Choose one Force-Sender input value displayed in the input setup:

Sender input 27: Effect 27: Longitudinal force

Invert input value Play override (normally set blank)

Second step (set range parameter)

Choose the minimal and maximal numerical value of the chosen Force-Sender input value. This will prevent spike values.

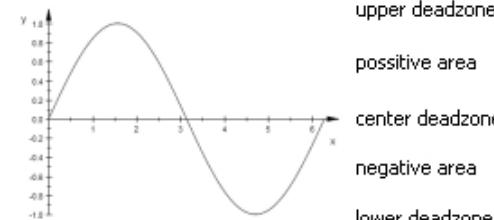

Maximum value 1500000

Minimum value 150

Split negative and positive

Minimum value - 100

Maximum value - 1000000

Use automatic maximum adjustment

Use automatic minimum adjustment (10%)

Third step (set influence to axis)

Choose intensity of this value to the axis in percent: 55 %

Adjust smoothness only, if your value is fidgety: (Current setting: off)
smooth movement is given in seconds from minimum to maximum value of this axis

weak/
off

smooth

add result value multiply result value overwrite result value

overwrite result if bigger than zero (used as trigger)
